Lecture Classification

Shenglan Du

Today's Agenda

- Previous Lecture: Supervised Learning
- Bayes Classification
 - Probability Basics
 - Bayes Classifier
- Linear Classification
 - Standard Linear Classifier
 - Logistic Classifier

Learning Objective

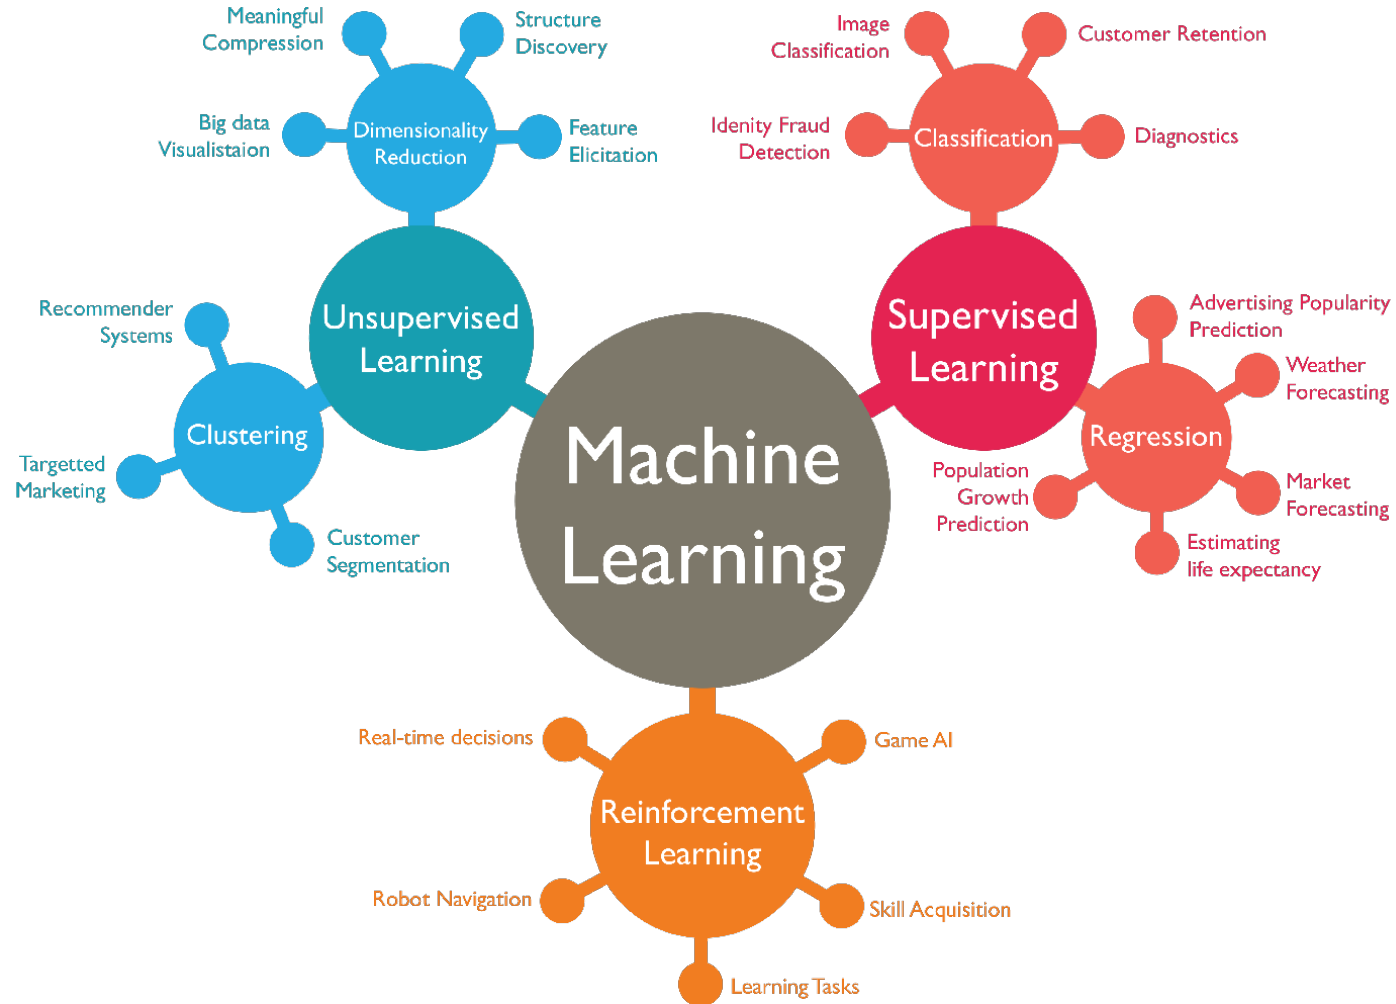

- Bayes Classification
 - Reproduce the Bayes rule
 - Apply Bayes classifier to solve a binary classification problem
 - Understand the concept of Bayes error
- Linear Classifiers
 - Explain the principles of standard linear classifier and logistic regression
 - Reproduce the objective function of logistic regression
 - Analyze the pros and cons of the two linear classifiers

Today's Agenda

- Previous Lecture: Supervised Learning 
- Bayes Classification
 - Probability Basics
 - Bayes Classifier
- Linear Classification
 - Standard Linear Classifier
 - Logistic Classifier

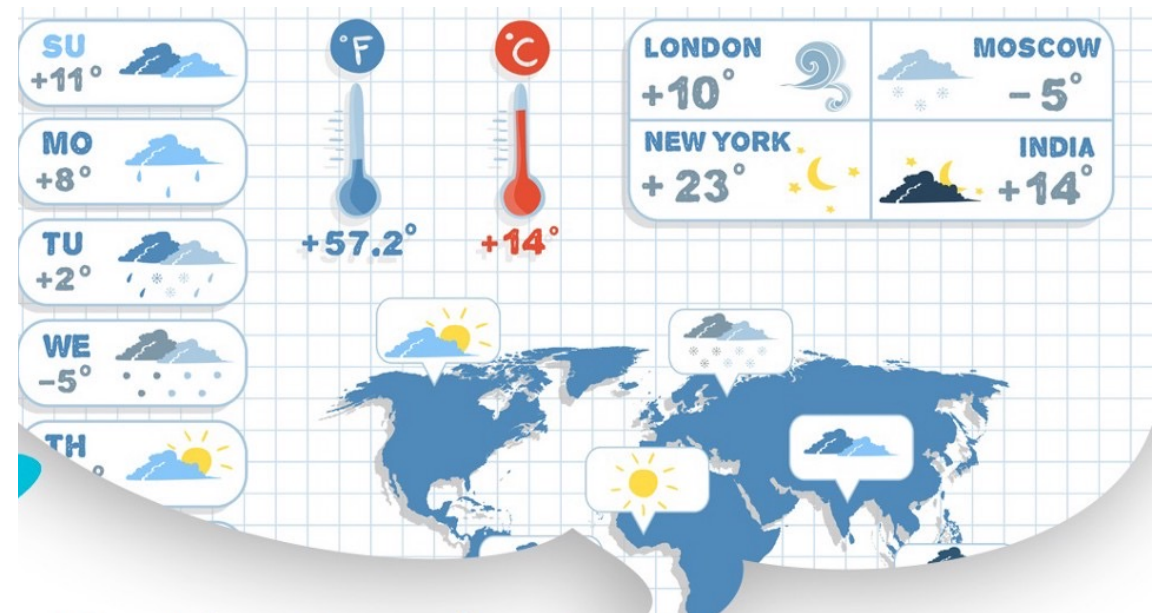

Supervised Learning

Supervised Learning

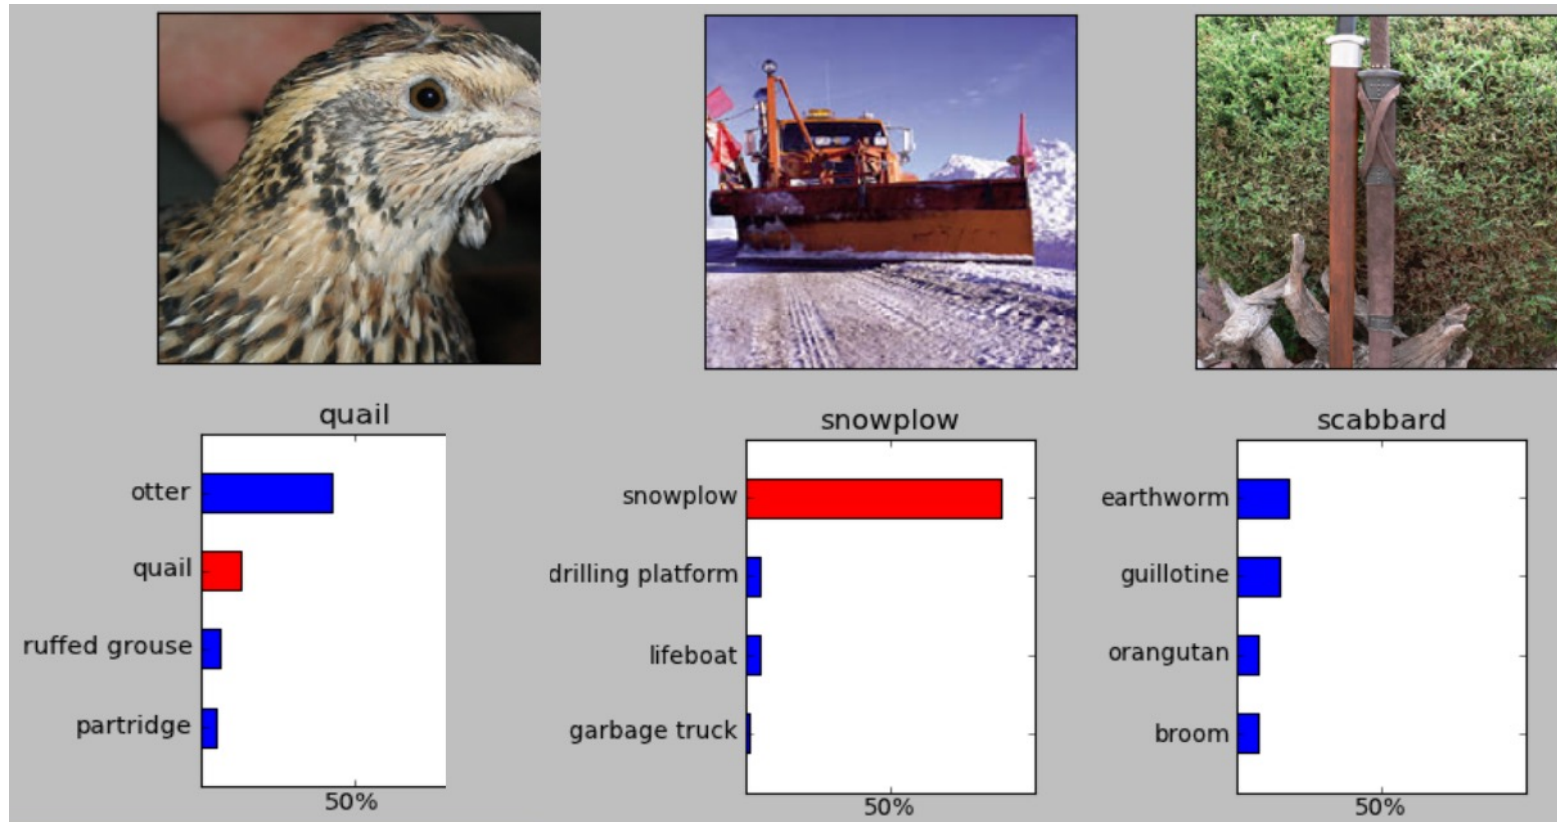

- An example: weather forecasting

Supervised Learning

- An example: image analysis

Supervised Learning: Classification

- Given a set of input data represented as feature vectors:

$$\mathbf{x} = (x_1, x_2, x_3 \dots x_p)^T$$

- Classification aims to specify which category/class \mathbf{y} some input data \mathbf{x} belong to

Supervised Learning: Classification

$$\mathbf{x} = (x_1, x_2, x_3 \dots x_p)^T$$

- P indicates the feature space dimension:
 - 1D feature space:

- 2D feature space:

y : ● Positive class
● Negative class

Supervised Learning: Classification

- An example of point cloud semantic classification

$$\mathbf{x} = (x, y, z, r, g, b, intensity \dots)^T$$

- \mathbf{y} :
- High vegetation
 - Low vegetation
 - Building
 - Road
 - Grass land

Supervised Learning: Classification

- Two classification approaches:
 - ***Generative approach***: model the probability distribution of feature x and label y
 - Bayes classifier
 - Gaussian mixture model
 - ***Discriminant functions***: model a function that directly map from feature x to label y
 - Linear classifier (Logistic regression, SVM)
 - Non-linear classifier (Decision tree, Neural networks)

Today's Agenda

- Previous Lecture: Supervised Learning
- **Bayes Classification** 
 - Probability Basics
 - Bayes Classifier
- Linear Classification
 - Standard Linear Classifier
 - Logistic Classifier

Bayes Classification

- A simple scenario: A tree or a building?

Image source 1: https://en.wikipedia.org/wiki/Tree#/media/File:Ash_Tree_-_geograph.org.uk_-_590710.jpg

Image source 2: https://en.wikipedia.org/wiki/Wilder_Building#/media/File:WilderBuildingSummerSolstice.jpg

Bayes Classification

- A simple scenario:
 - Buildings have planar surfaces
 - Trees have noisy, near round surfaces
- The machine detected that the input object has planar surfaces. What the object do you guess to be?

Bayes Classification

- It's very likely to be a building
- But how do machines interpretate the word "likely"?

Today's Agenda

- Previous Lecture: Supervised Learning
- Bayes Classification
 - Probability Basics 
 - Bayes Classifier
- Linear Classification
 - Standard Linear Classifier
 - Logistic Classifier

Probability Basics

- Product rule:

$$P(X, Y) = P(X) P(Y|X)$$

- Bayes rule:

$$P(Y) P(X|Y) = P(X) P(Y|X)$$

$$P(Y|X) = \frac{P(Y) P(X|Y)}{P(X)}$$

Probability Basics

- Given feature \mathbf{x} and label y

$$P(y|\mathbf{x}) = \frac{P(y) P(\mathbf{x}|y)}{P(\mathbf{x})}$$

- $P(\mathbf{x}|y)$: class conditional probability
- $P(y)$: class prior probability
- $P(y|\mathbf{x})$: class posterior probability

Probability Basics

- Assume equal priors for both buildings and trees

$$P(y = b) = P(y = t) = 0.5$$

Probability Basics

- Assume we have the class conditional probabilities as follows

$$P(x = \textit{planar} | y = b) = 0.8$$

$$P(x = \textit{round} | y = b) = 0.2$$

$$P(x = \textit{planar} | y = t) = 0.25$$

$$P(x = \textit{round} | y = t) = 0.75$$

Probability Basics

- building:

$$P(y = b | x = \textit{planar}) =$$

- tree:

$$P(y = t | x = \textit{planar}) =$$

Probability Basics

- building:

$$\begin{aligned} P(y = b|x = \textit{planar}) &= \frac{P(y = b) P(x = \textit{planar}|y = b)}{P(x = \textit{planar})} \\ &= \frac{0.5 * 0.8}{P(x = \textit{planar})} \end{aligned}$$

- tree:

$$\begin{aligned} P(y = t|x = \textit{planar}) &= \frac{P(y = t) P(x = \textit{planar}|y = t)}{P(x = \textit{planar})} \\ &= \frac{0.5 * 0.25}{P(x = \textit{planar})} \end{aligned}$$

Probability Basics

- Prior:

$$P(y = b) = P(y = t)$$

- Posterior:

$$P(y = t|x = \textit{planar}) \ll P(y = b|x = \textit{planar})$$

Today's Agenda

- Previous Lecture: Supervised Learning
- Bayes Classification
 - Probability Basics
 - Bayes Classifier 
- Linear Classification
 - Standard Linear Classifier
 - Logistic Classifier

Bayes Classifier

- Step 1: estimate the class conditional probabilities
- Step 2: multiply with class priors
- Step 3: compute the class posterior probabilities

Bayes Classifier

- Step 4: find the classification boundary

Bayes Classifier

- The Bayes rule provides an approach of describing the uncertainty quantitatively, allowing for **the optimal prediction given the observations present**
- Bayes serves as the foundation for the modern machine learning

Bayes Error

- All models are wrong but some are useful...So where can the error happen?

Bayes Error

- Where is the error?
 - All trees have spherical surfaces
 - All buildings have cube-shapes
 - All rabbits have long ears
 - All sheeps are black
 -

Bayes Error

- So where can the error happen?

Bayes Error

$$P(e) = \int_{-\infty}^{x_0} p(x|y_2)P(y_2) + \int_{x_0}^{\infty} p(x|y_1)P(y_1)$$

Bayes Error

- It's the minimum attainable error using any kinds of existing models (SVM, RF, Neural networks)
- It doesn't depend on the ML model that you apply, but only on the data distribution
- We cannot obtain it as we don't have true distributions of real world

Minimizing the Risk

- Healthy or ill?
 - Assigning “ill” to a healthy person will cause panic to the patient
 - Assigning “healthy” to an ill person has more severe outcome

Minimizing the Risk

- Assume: $y_1 = \text{healthy}$, $y_2 = \text{ill}$, λ_{ij} is the cost of assign “j” label to class i

- Classifying with risk we have:

- Assign \mathbf{x} to y_1 if

$$\lambda_{21}p(\mathbf{x}|y_2)P(y_2) < \lambda_{12}p(\mathbf{x}|y_1)P(y_1)$$

- Assign \mathbf{x} to y_2 otherwise

Today's Agenda

- Previous Lecture: Supervised Learning
- Bayes Classification
 - Probability Basics
 - Bayes Classifier
- **Linear Classification** 
 - Standard Linear Classifier
 - Logistic Classifier

Linear Classification

- Review Linear Regression:

Linear Classification

- Review Linear Regression:
 - Model?
 - Solution?
 - How do you find the solution?

Linear Classification

- Review Linear Regression:

$$y_i = \mathbf{w}^T \mathbf{x}_i + b$$

- Solution can be found by gradient descent searching
- A close form solution:

$$(\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{Y}$$

Linear Classification

- Link the output y to some classification codes

$$y = \mathbf{w}^T \mathbf{x} + b$$

- $y = \text{const}$ determines a decision boundary
- A decision boundary is a $(D-1)$ dimension hyperplane of D dimension input feature space

Today's Agenda

- Previous Lecture: Supervised Learning
- Bayes Classification
 - Probability Basics
 - Bayes Classifier
- Linear Classification
 - Standard Linear Classifier 
 - Logistic Classifier

Standard Linear Classifier

Standard Linear Classifier

- By fitting a linear line of $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ s.t.

$$y_i = \begin{cases} +1, & \text{if the class is positive} \\ -1, & \text{if the class is negative} \end{cases}$$

- We obtain the linear decision boundary of the input space

Standard Linear Classifier

- Solution can also be given by least squares

Standard Linear Classifier

- Minimizing square errors can be sensitive to data distribution

Today's Agenda

- Previous Lecture: Supervised Learning
- Bayes Classification
 - Probability Basics
 - Bayes Classifier
- Linear Classification
 - Standard Linear Classifier
 - Logistic Classifier 

Logistic Classifier

- Also known as logistic regression, although it is a model for classification rather than regression.....
- Trick: link the probabilities to something linear

$$\log \left(\frac{P(y|\mathbf{x})}{1 - P(y|\mathbf{x})} \right) = \mathbf{w}^T \mathbf{x} + b$$

Logistic Classifier

$$\log \left(\frac{P(y|\mathbf{x})}{1 - P(y|\mathbf{x})} \right) = \mathbf{w}^T \mathbf{x} + b$$

- What is $P(y|\mathbf{x})$?

Logistic Classifier

$$P(y|\mathbf{x}) = \frac{1}{e^{-(\mathbf{w}^T \mathbf{x} + b)} + 1}$$

- Can be rewritten as:

$$P(y|\mathbf{x}) = \sigma(\mathbf{w}^T \mathbf{x} + b)$$

$$\sigma(f) = \frac{1}{e^{-f} + 1}$$

Logistic sigmoid function

Logistic Classifier

- Overall objective function: to maximize

$$P(\mathbf{y}|\mathbf{x}) = P(y_1|\mathbf{x}_1)P(y_2|\mathbf{x}_2) \dots P(y_n|\mathbf{x}_n)$$

- Which equals to maximizing:

$$\log P(\mathbf{y}|\mathbf{x}) = \sum_{i=1}^n \log P(y_i|\mathbf{x}_i)$$

Logistic Classifier

- If $y_i = +1$,

$$P(y_i | \mathbf{x}_i) = \frac{1}{e^{-f(\mathbf{x}_i)} + 1}$$

- If $y_i = -1$,

$$P(y_i | \mathbf{x}_i) = 1 - \frac{1}{e^{-f(\mathbf{x}_i)} + 1} = \frac{1}{e^{f(\mathbf{x}_i)} + 1}$$

Logistic Classifier

$$\log P(\mathbf{y}|\mathbf{x}) = \sum_{i=1}^n \log \frac{1}{e^{-y_i f(x_i)} + 1} = - \sum_{i=1}^n \log(e^{-y_i f(x_i)} + 1)$$

- Therefore, the problem transfers to minimizing

$$\sum_{i=1}^n \log(e^{-y_i f(x_i)} + 1)$$

Logistic Classifier

$$\sum_{i=1}^n \log(e^{-y_i f(x_i)} + 1)$$

- Robust to outliers
- Can be solved by gradient descent
- No close form solution
- Solution depends on the initialization

Conclusions

- Many classification or regression problems can be specified as:
 - Find a suitable model / hypothesis
 - Define a loss function (i.e., least squares, maximum likelihood ...)
 - Feed the data samples into the model and find the model parameters that lead to the least loss
