Lesson 06
Point cloud processing

GEO1015.2025

Hugo Ledoux

Appendices of terrain book are important!

PC in text files

ASCII

PC in binary files: LAS

- LASer file format (LAS)
- most widely used standard for the dissemination of point cloud data.
- designed for datasets that originate from (airborne) lidar scanners.
- classes are fixed (but space for user-defined ones):

Code	Meaning
0	never classified
1	unclassified
2	ground
3	low vegetation
4	medium vegetation
5	high vegetation
6	building
7	low point (noise)
8	*reserved*
9	water
13–31	user-defined

Format 0

Table A.1: LAS Point Data Record Format 0

Field	Format	Length (bits)	Description
X	int	32	X coordinate
Y	int	32	Y coordinate
Z	int	32	Z coordinate
Intensity	unsigned int	16	The pulse return amplitude
Return number	unsigned int	3	The total pulse return number for a given output pulse
Number of returns	unsigned int	3	Total number of returns for a given pulse
Scan Direction Flag	boolean	1	Denotes the direction at which the scanner mirror was travelling at the time of the output pulse. A bit value of 1 is a positive scan direction, and a bit value of 0 is a negative scan direction (where positive scan direction is a scan moving from the left side of the in-track direction to the right side and negative the opposite).
Edge of Flight Line	boolean	1	Has a value of 1 only when the point is at the end of a scan. It is the last point on a given scan line before it changes direction.
Classification	unsigned int	5	Classification code
Scan Angle Rank	int	4	The angle at which the laser pulse was output from the scanner including the roll of the aircraft
User Data	unsigned int	4	May be used at the user's discretion
Point Source ID	unsigned int	8	Indicates the file from which this point originated Non-zero if this point was copied from another file

$$X_{coordinate} = (X_{record} * X_{scale}) + X_{offset}$$
$$Y_{coordinate} = (Y_{record} * Y_{scale}) + Y_{offset}$$
$$Z_{coordinate} = (Z_{record} * Z_{scale}) + Z_{offset}$$

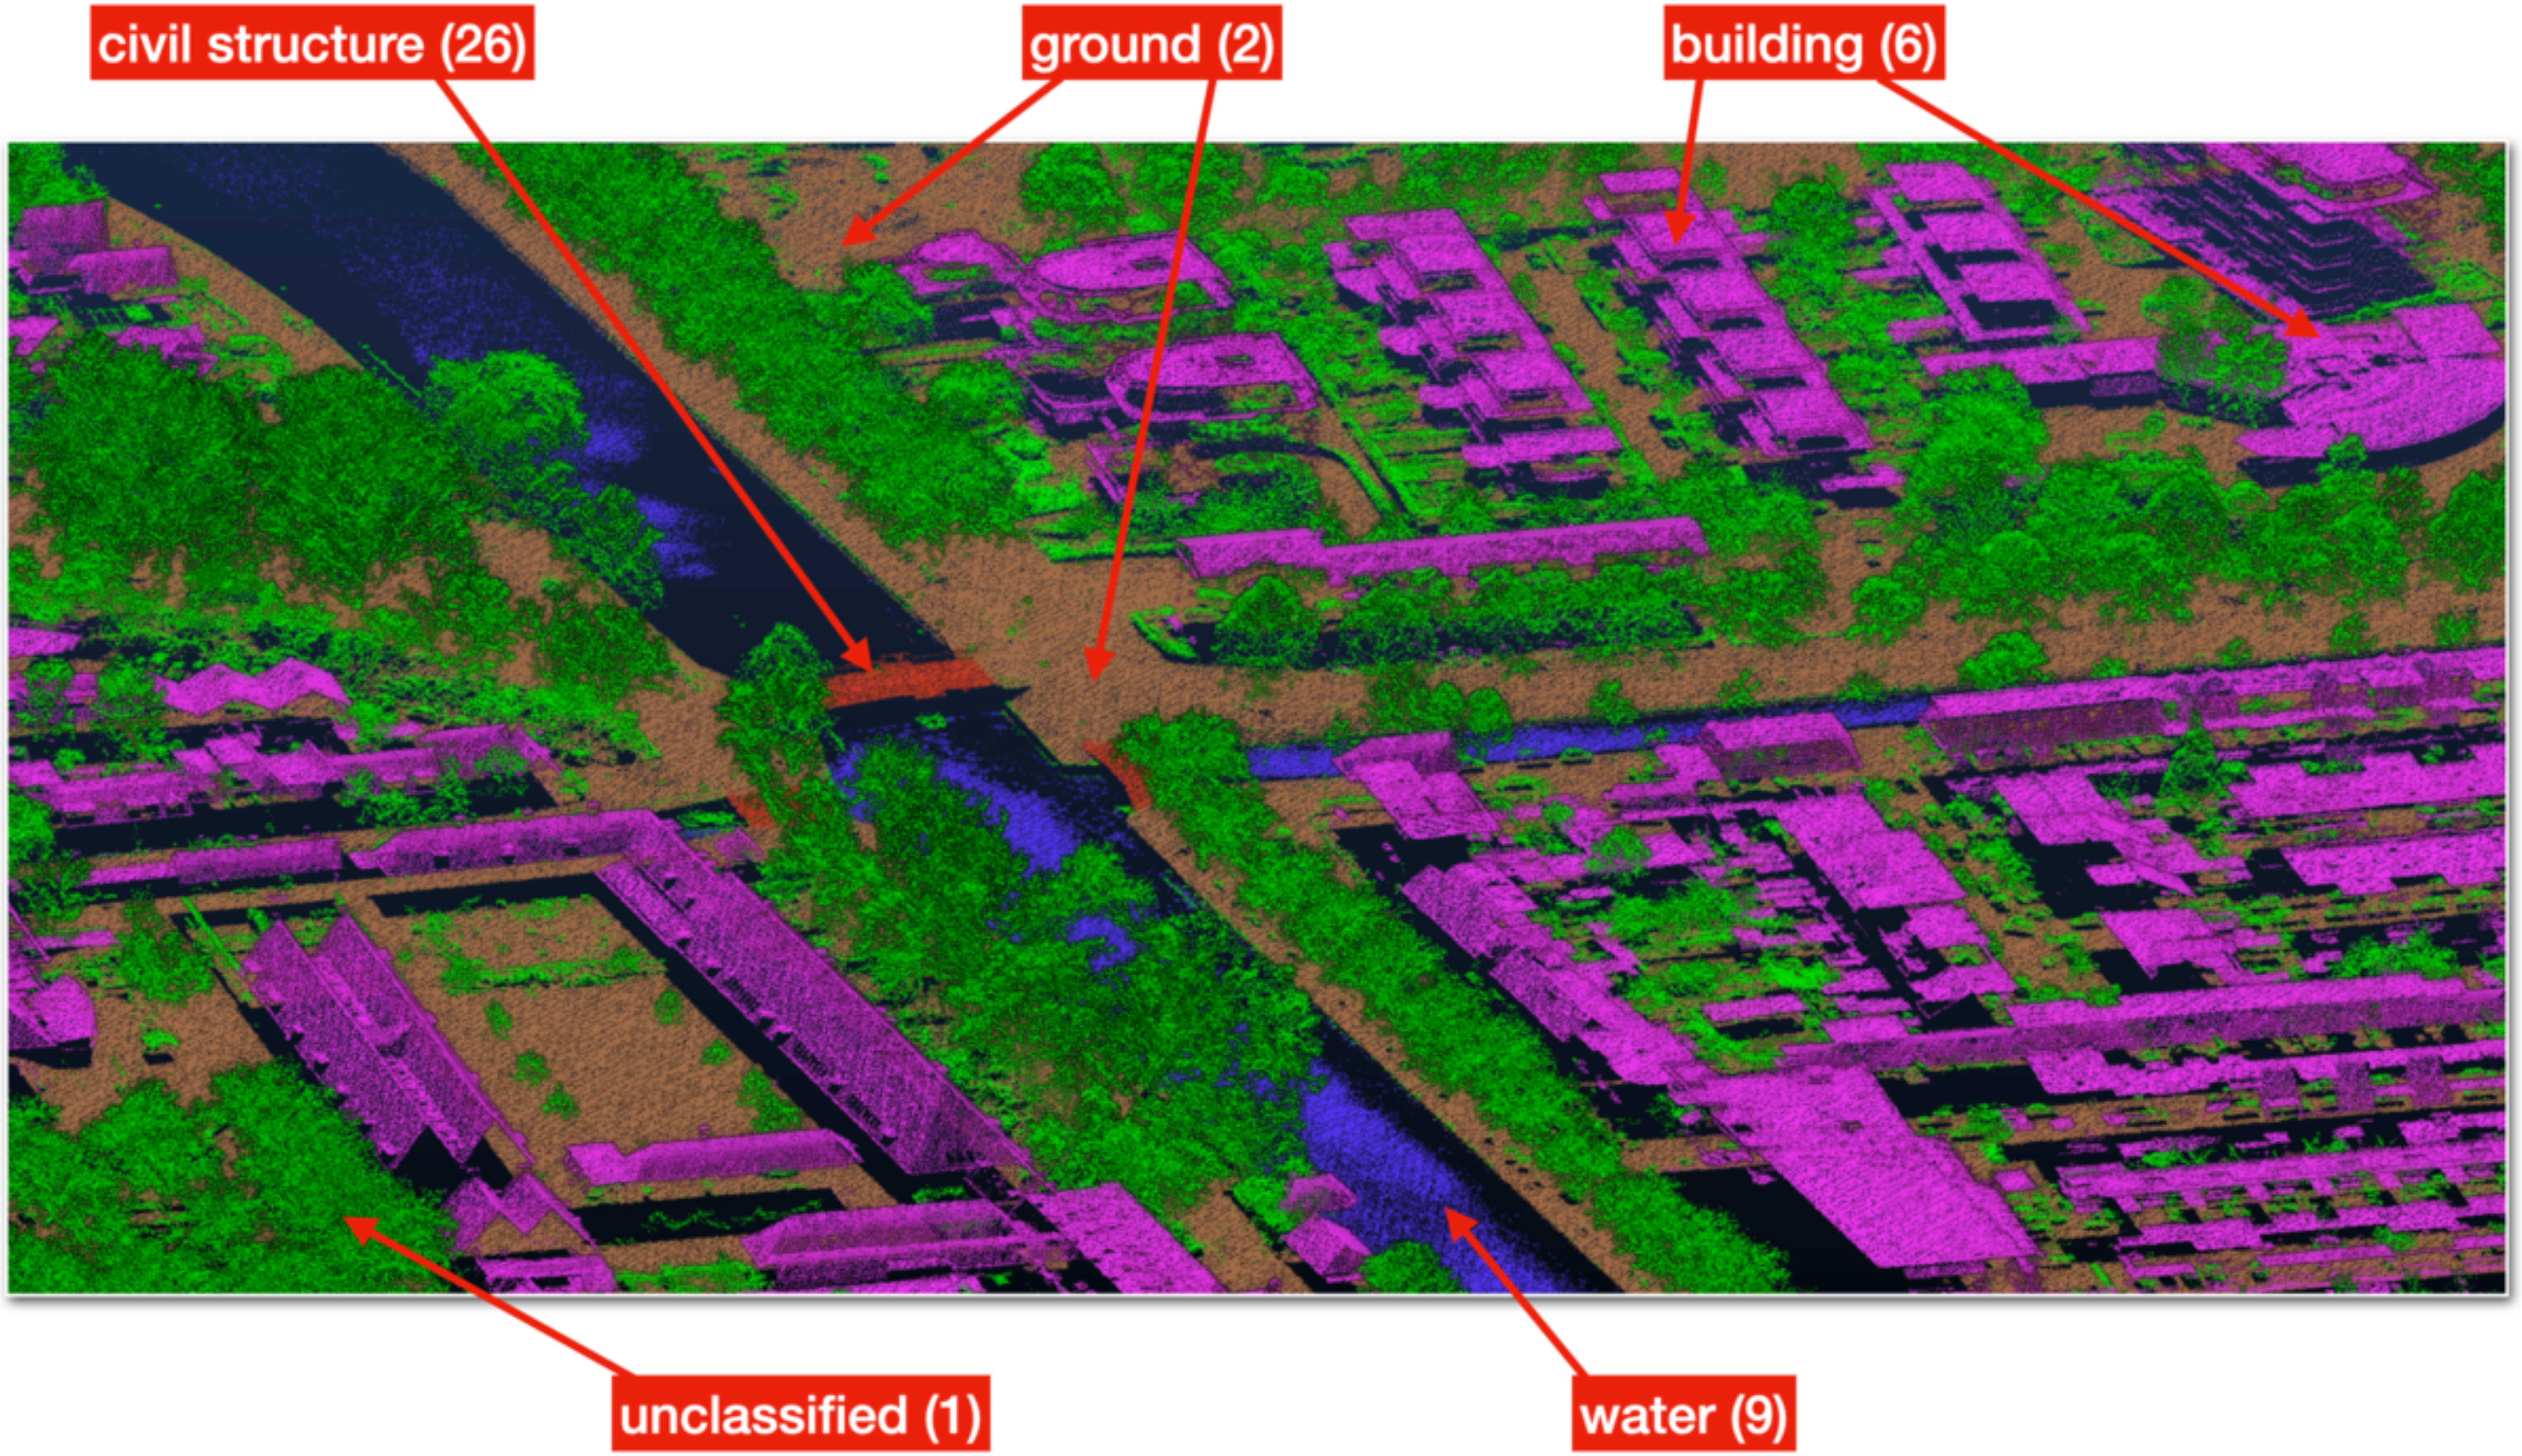
Compressed LAS == LAZ

- Compression == 10X I'd say: try with AHN4!
- point records are grouped in blocks of 50,000 records
- Each block is individually compressed, which makes it possible to partially decompress only the needed blocks from a file (instead of always needing to decompress the whole file).
- a greater compression factor can often be achieved after spatially sorting the points.
- Read/write is slower…

Not an official standard!

!= zLAS

AHN4+5 classification

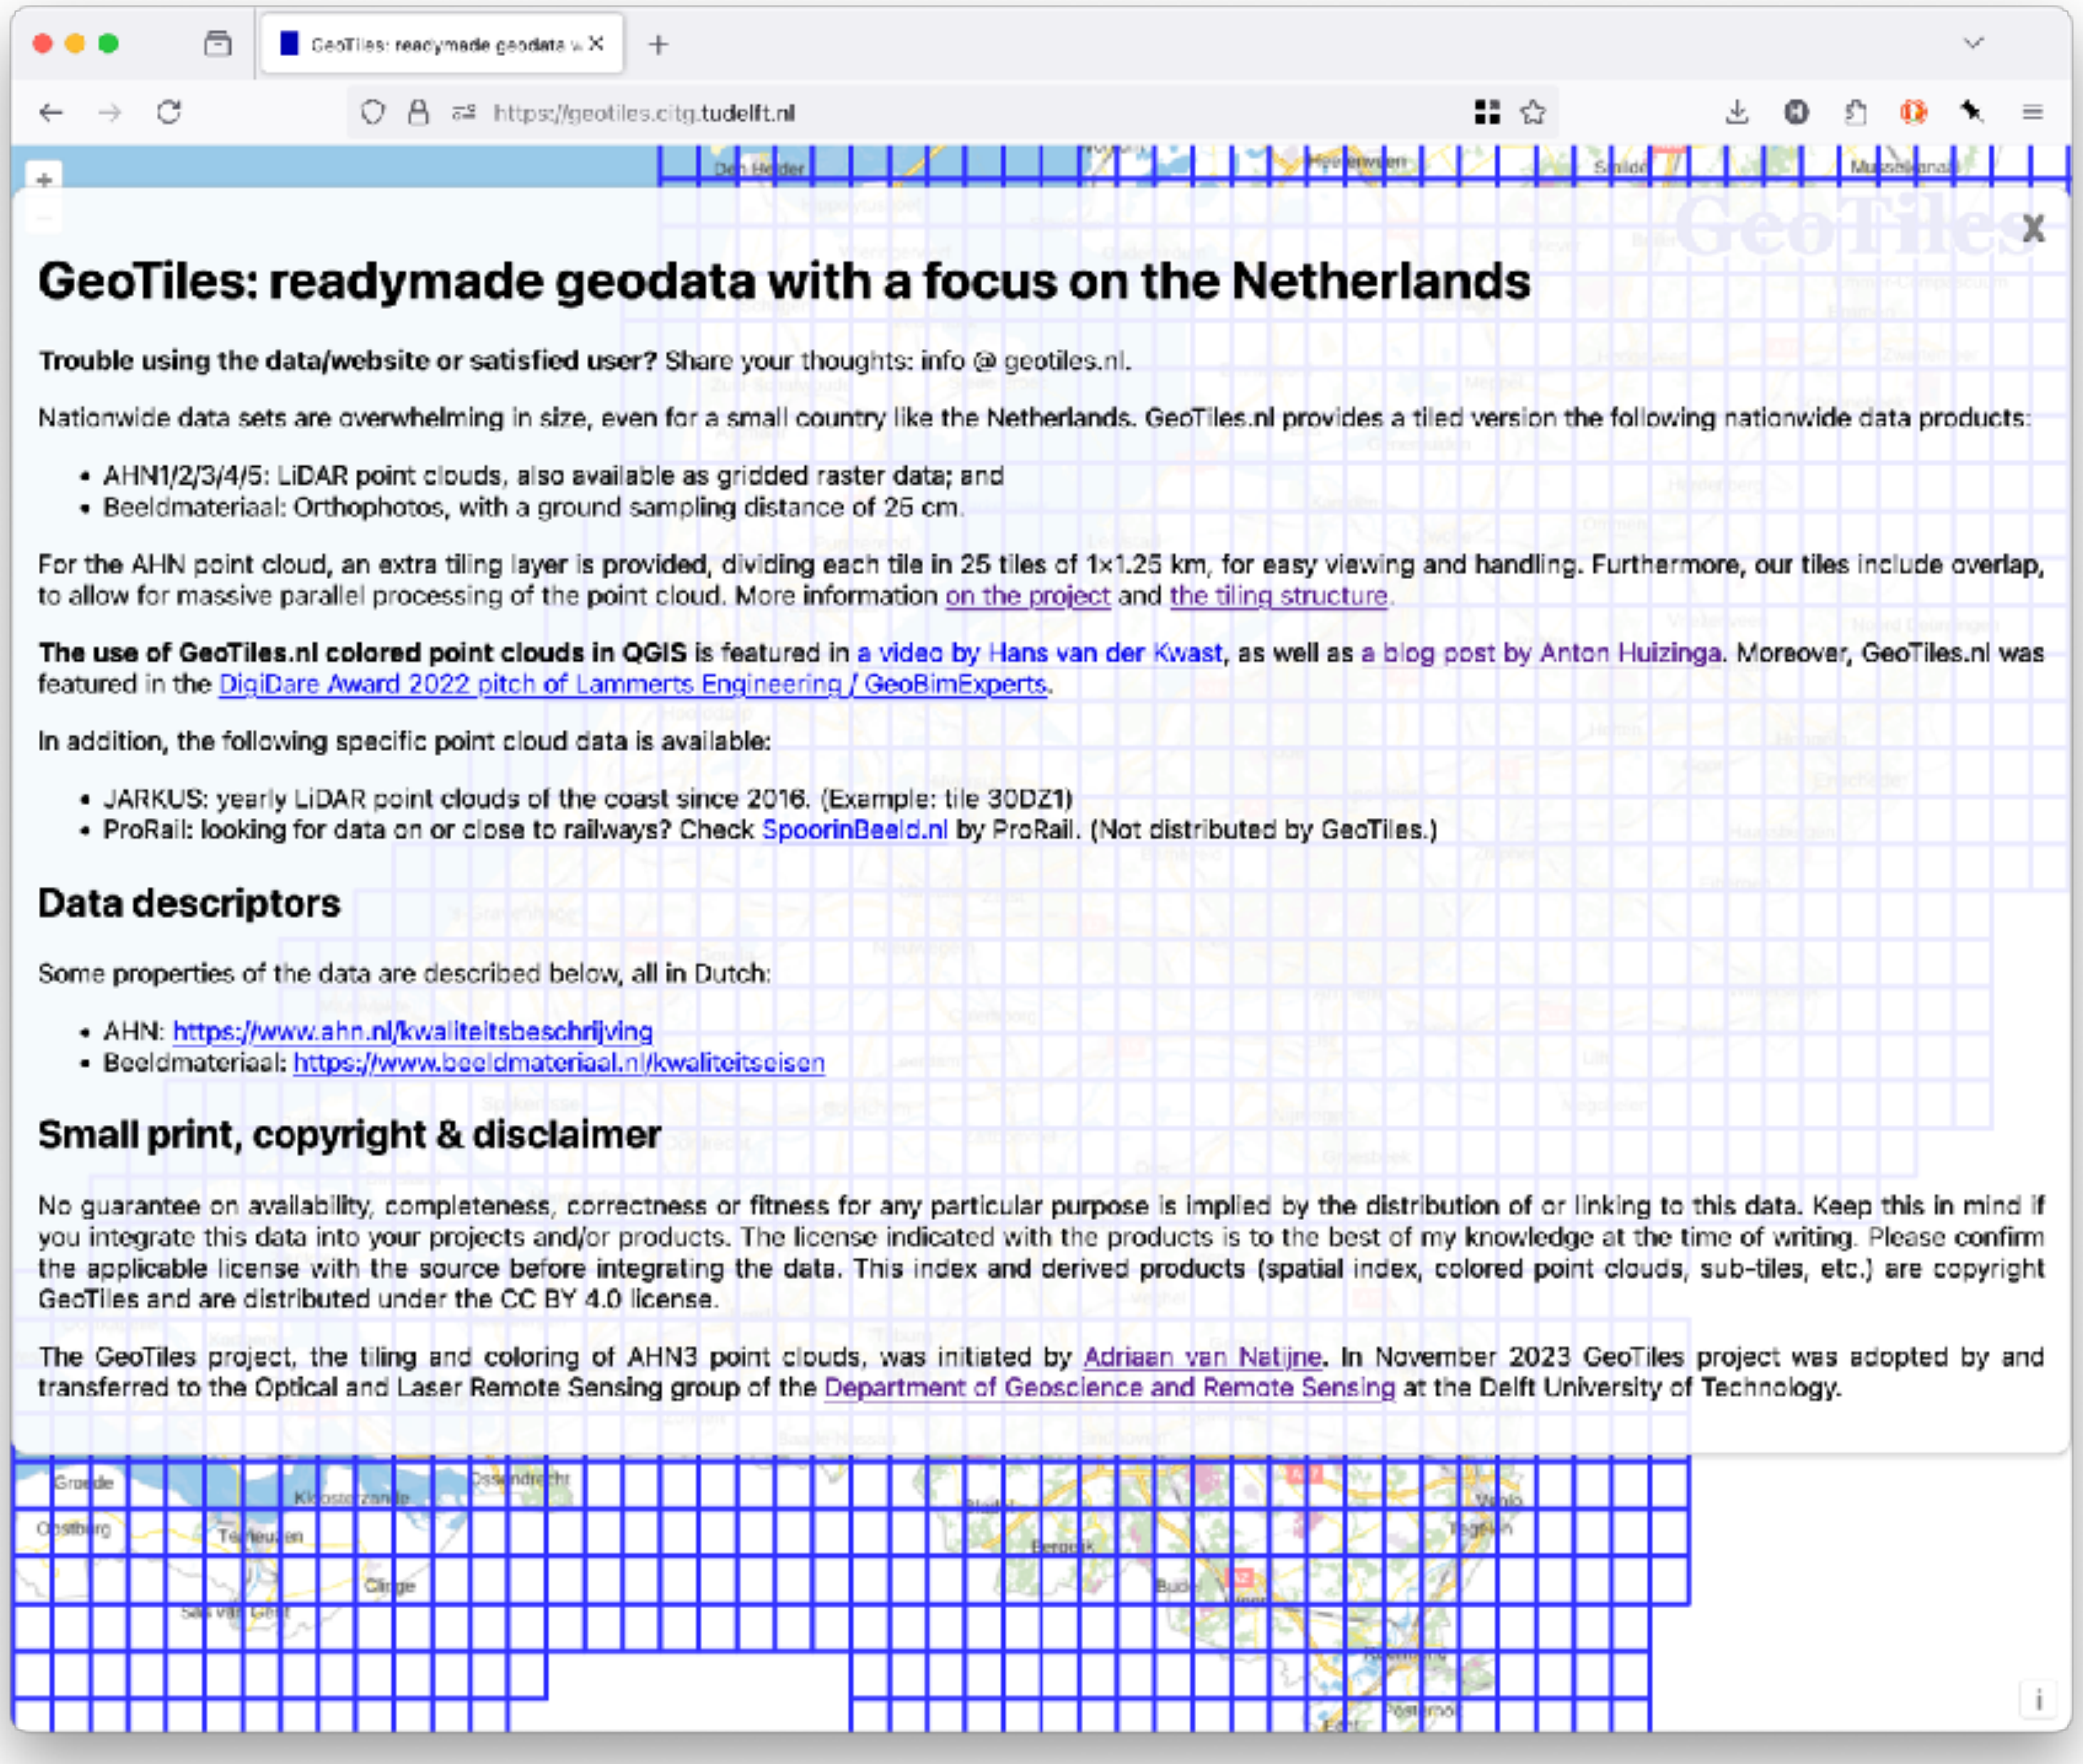


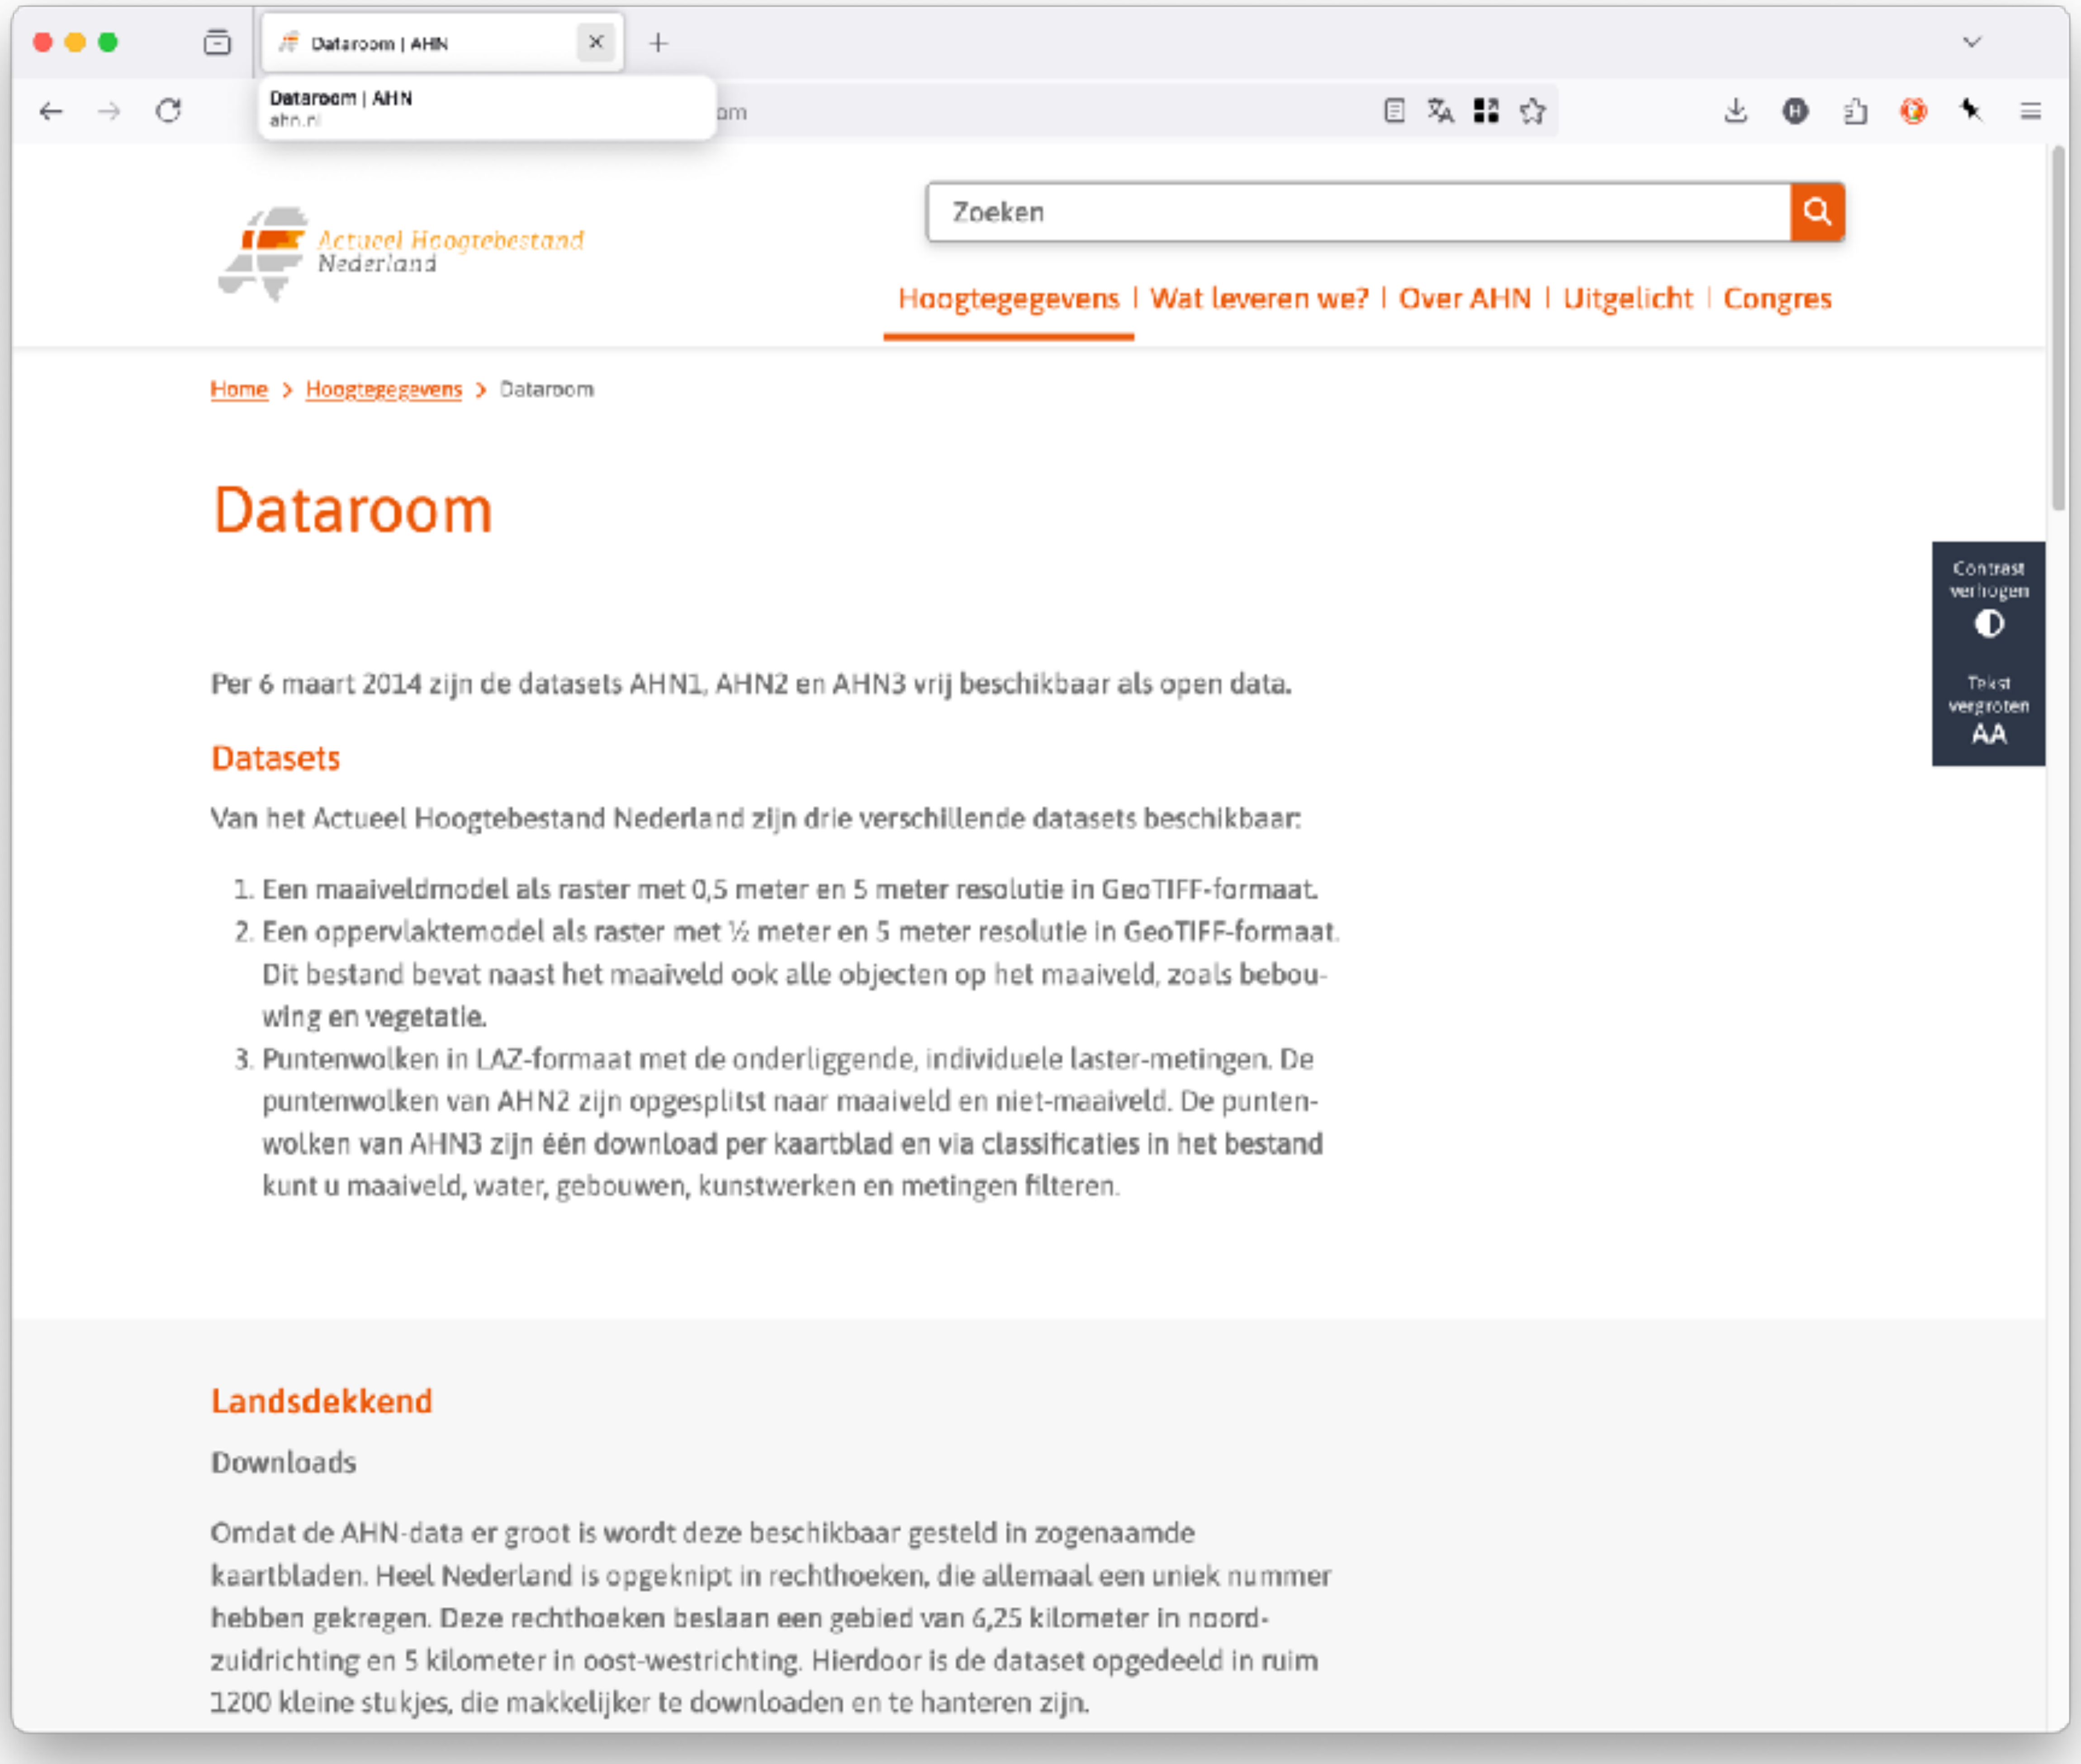
Class 1
=
unclassified
(includes many things!)

Class 14
=
High-volatage
pylons+cables

Class 26
=
bridges, statues, and
viaducts

You want to download AHN?



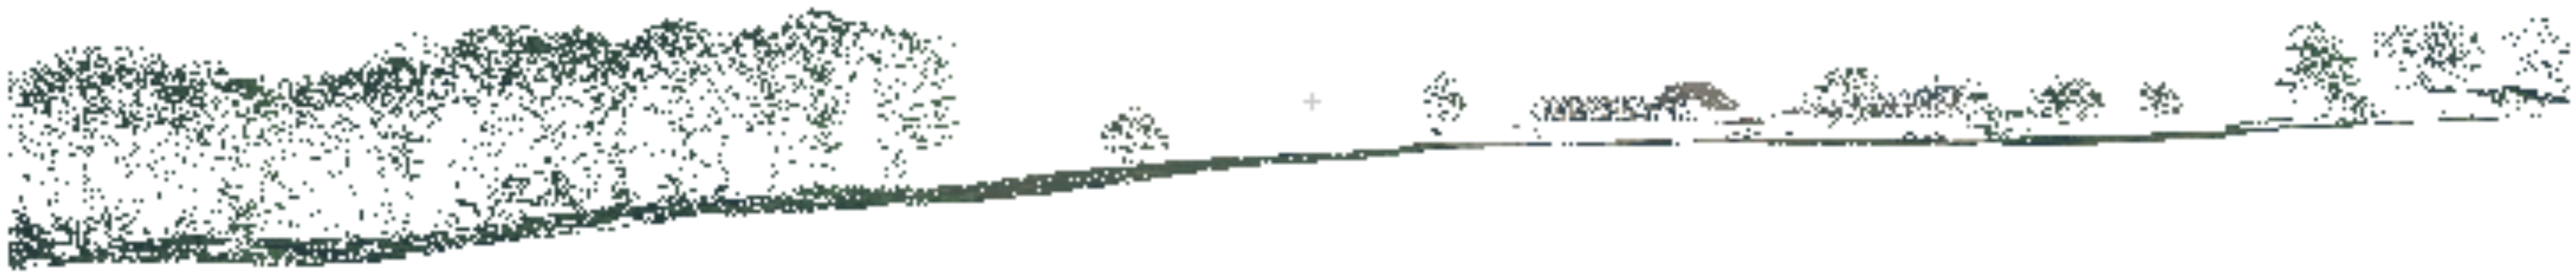


Thinning

- **random:** randomly keep a given percentage of the points, eg 10%.
- ***n*th-point:** keep only the nth point in the dataset. For instance, if $n = 100$, we would keep the 1st, the 101th, the 201th, etc; a dataset with 100 000 points is reduced to 1000 points. This is the quickest thinning method.
- ***n*th-point random:** if there is some structure in the input points (eg if generated from a gridded terrain) then nth-point could create datasets with artefacts. The randomised variation chooses randomly in the n points one point.
- **grid:** overlay a 2D or 3D regular grid over the points and keep m points per grid cell. That can be one of the original points, an average of those, or the exact centre of the cell. The thinning factor depends on the chosen cell-size. Notice that the result is often a point cloud with a homogeneous point density on all surfaces (only on the horizontal surfaces if a 2D grid is used).

Ground filtering

This does not use the classification, only geometry!

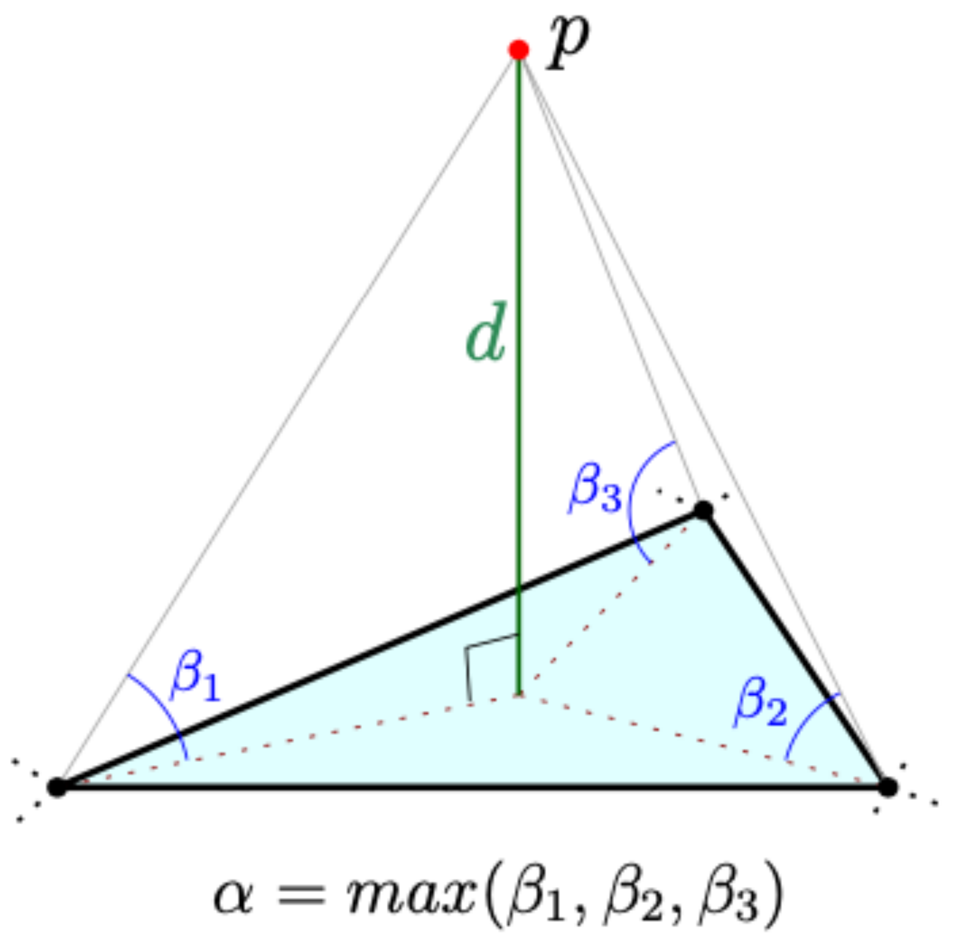


(a) Original point cloud

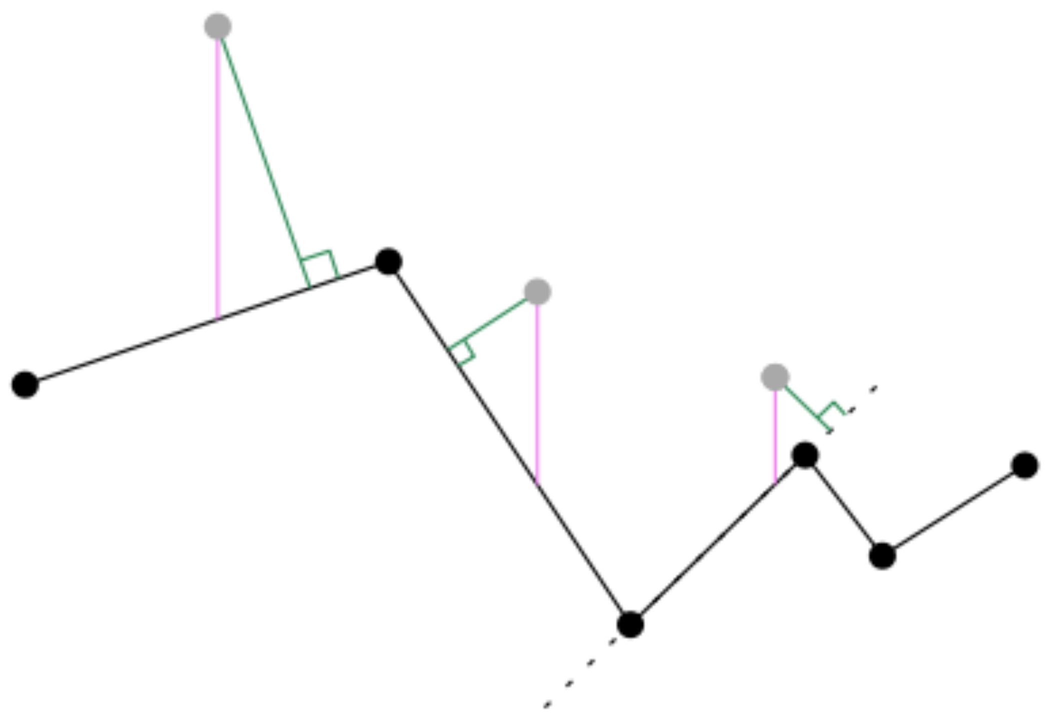
(b) After ground filtering

Method #1: Ground filtering with TIN (GFTIN)

1. construction of a rudimentary initial TIN (usually a Delaunay TIN);
2. computation of two geometric properties for each point that is not already labelled as ground;
3. incremental insertion of points that pass a simple and local 'ground test' based on the computed geometric properties.



(a) The two ground filter criteria: d and α.



(b) Profile view of a TIN with the vertical projections (pink) and the closest distances to the plane (green) shown for 3 different points. Notice that it is possible that the closest projection falls outside the triangle, as shown for the point on the right.

Figure 11.5: Ground filtering with a TIN.

Method #2: Cloth simulation filter (CSF)

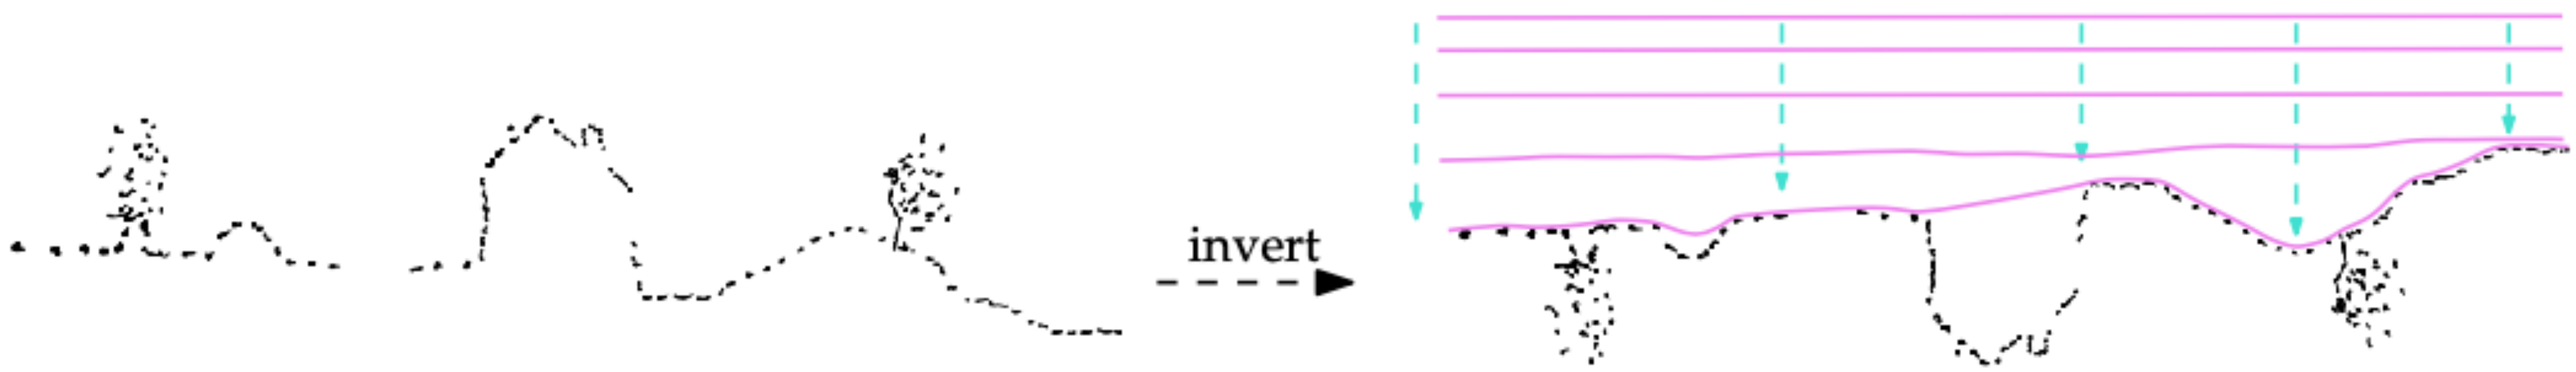


Figure 11.6: Basic idea behind the CSF algorithm for ground filtering of a point cloud: inverting the data and letting a cloth fall.

Method #2: Cloth simulation filter (CSF)

Two factors influence the z-value of a particle during the cloth falling process:

1. **external forces:** in this case this is the gravity pulling down a particle;
2. **internal forces:** the tension in the cloth, which is modelled by the interactions between a particle and its neighbours.

As particles fall down, some will reach the ground and become *unmovable*. These will potentially be neighbours to *movable* ones, whose elevation will be controlled by how we define the rigidity of the cloth.

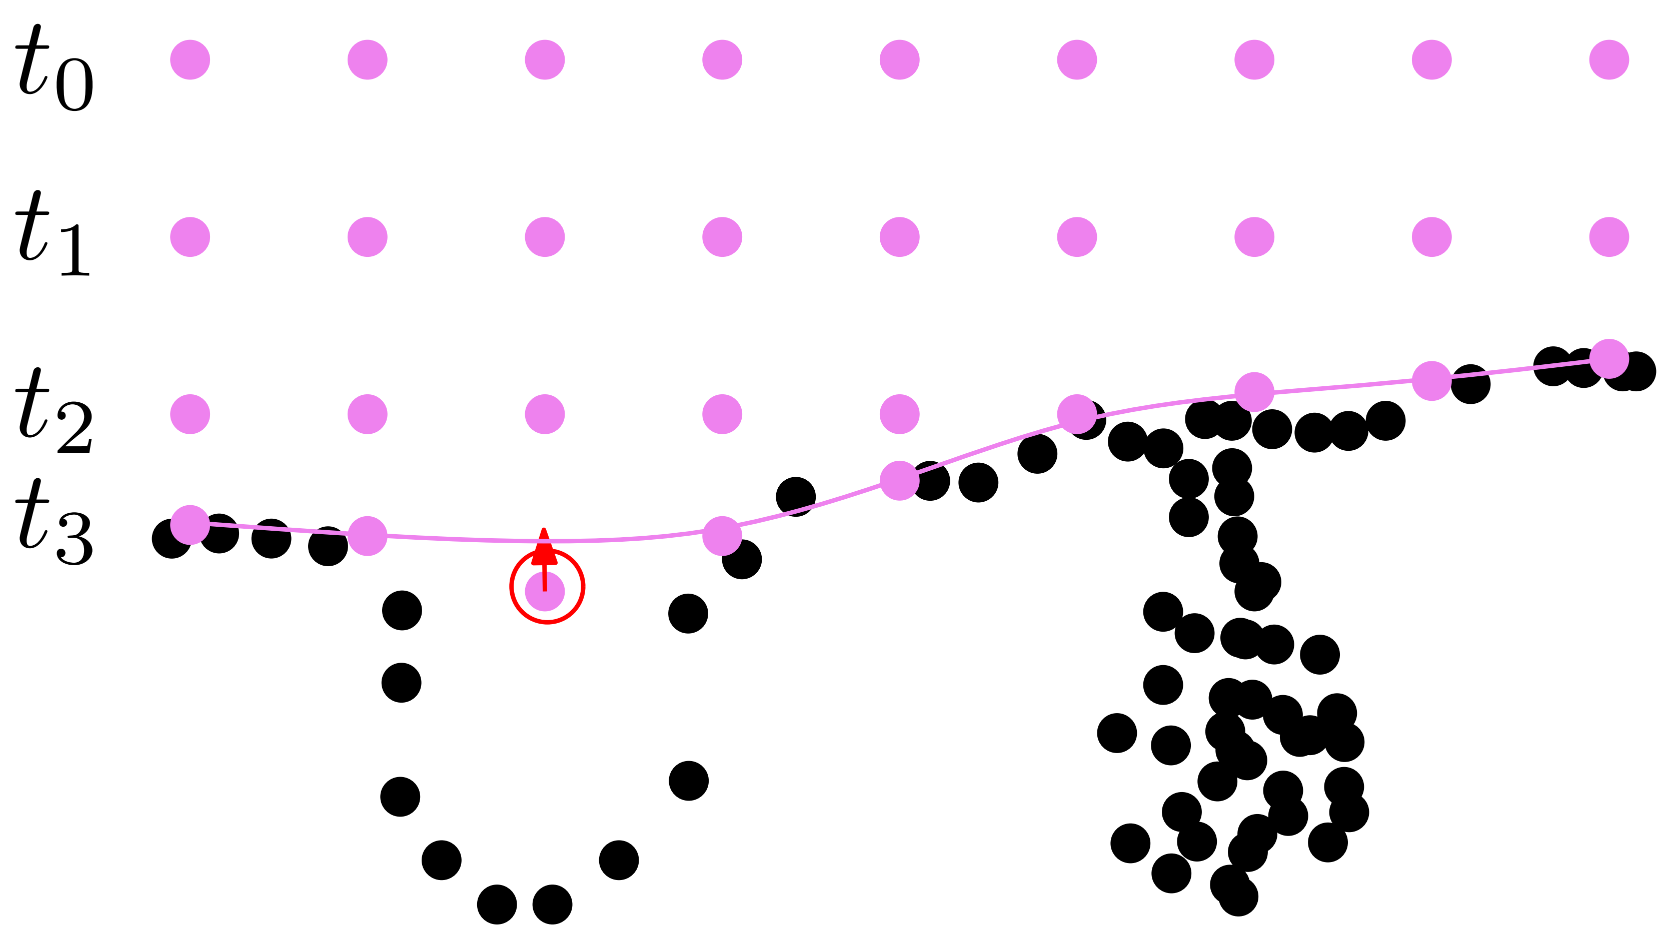

Figure 11.7

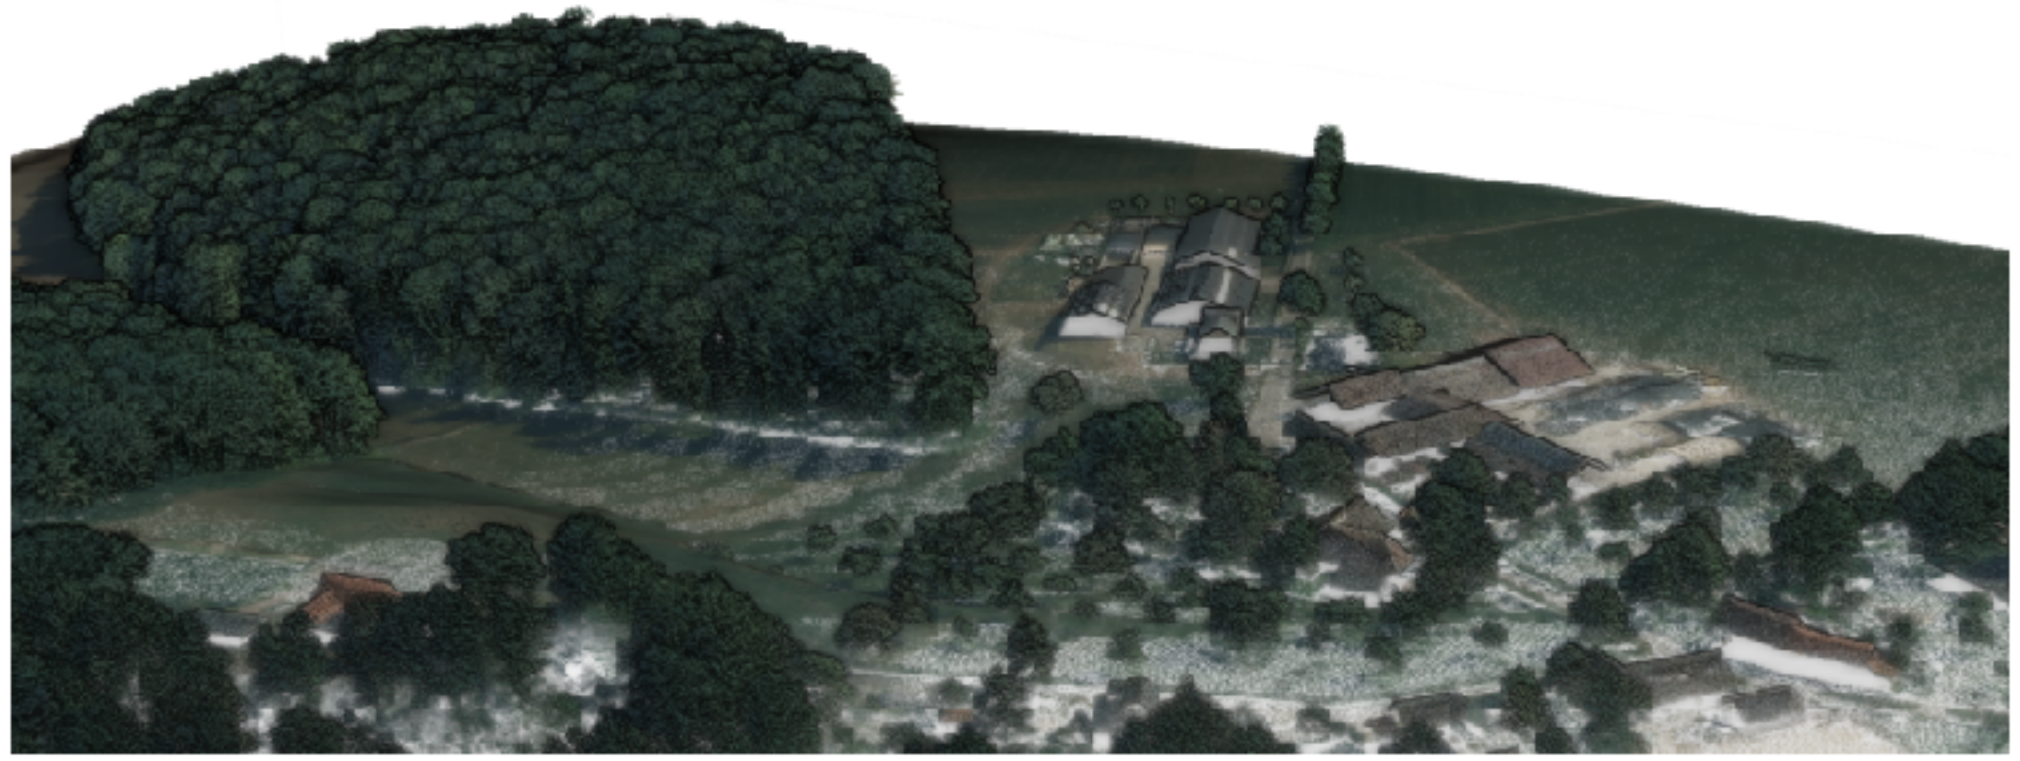
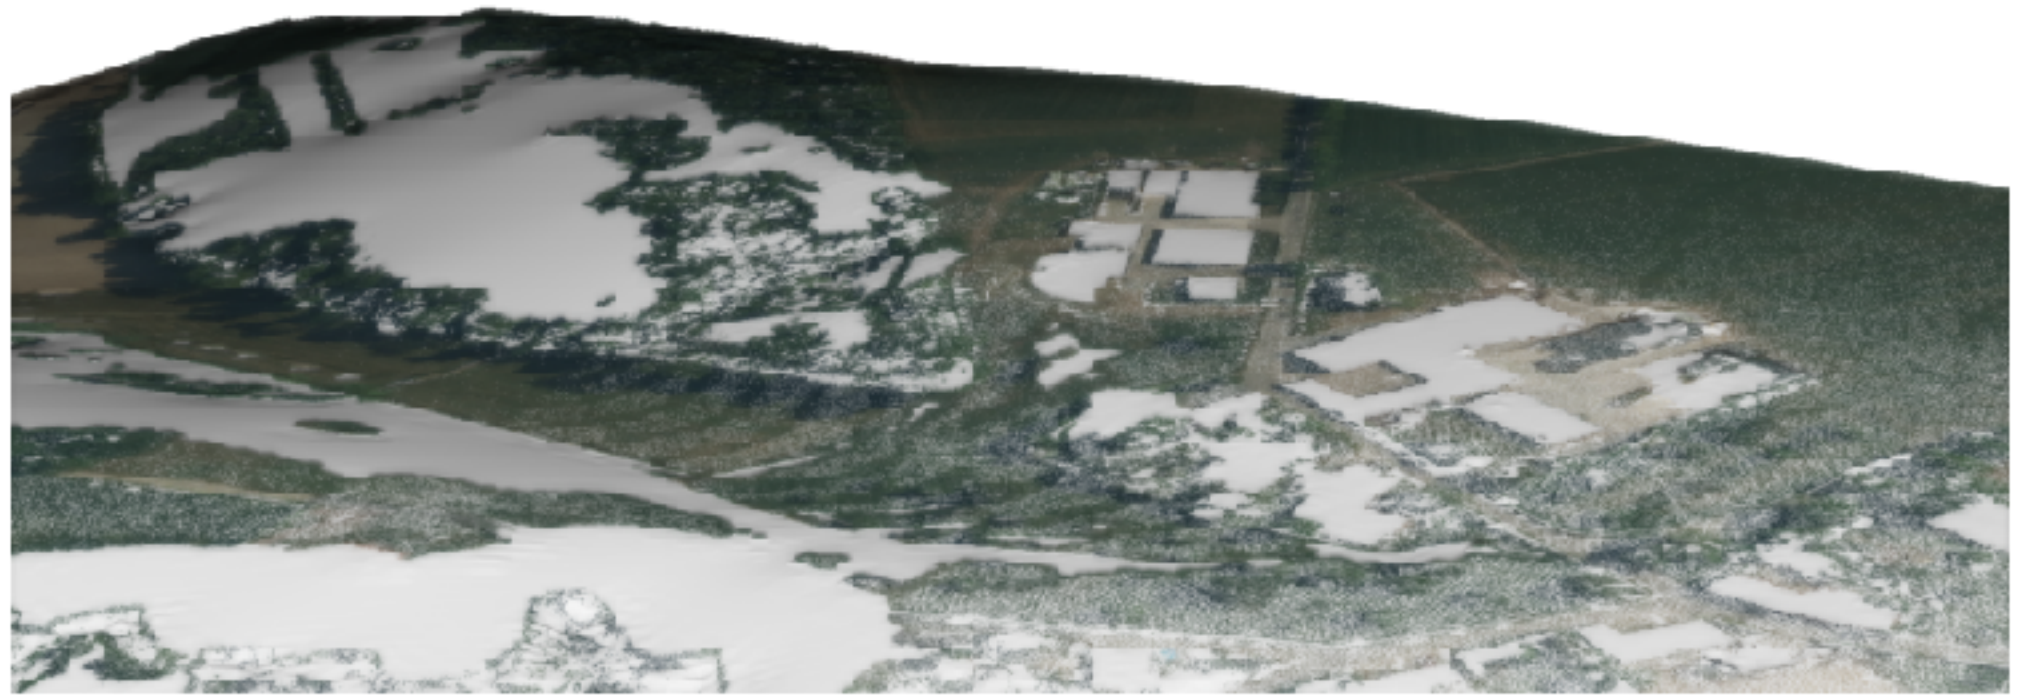
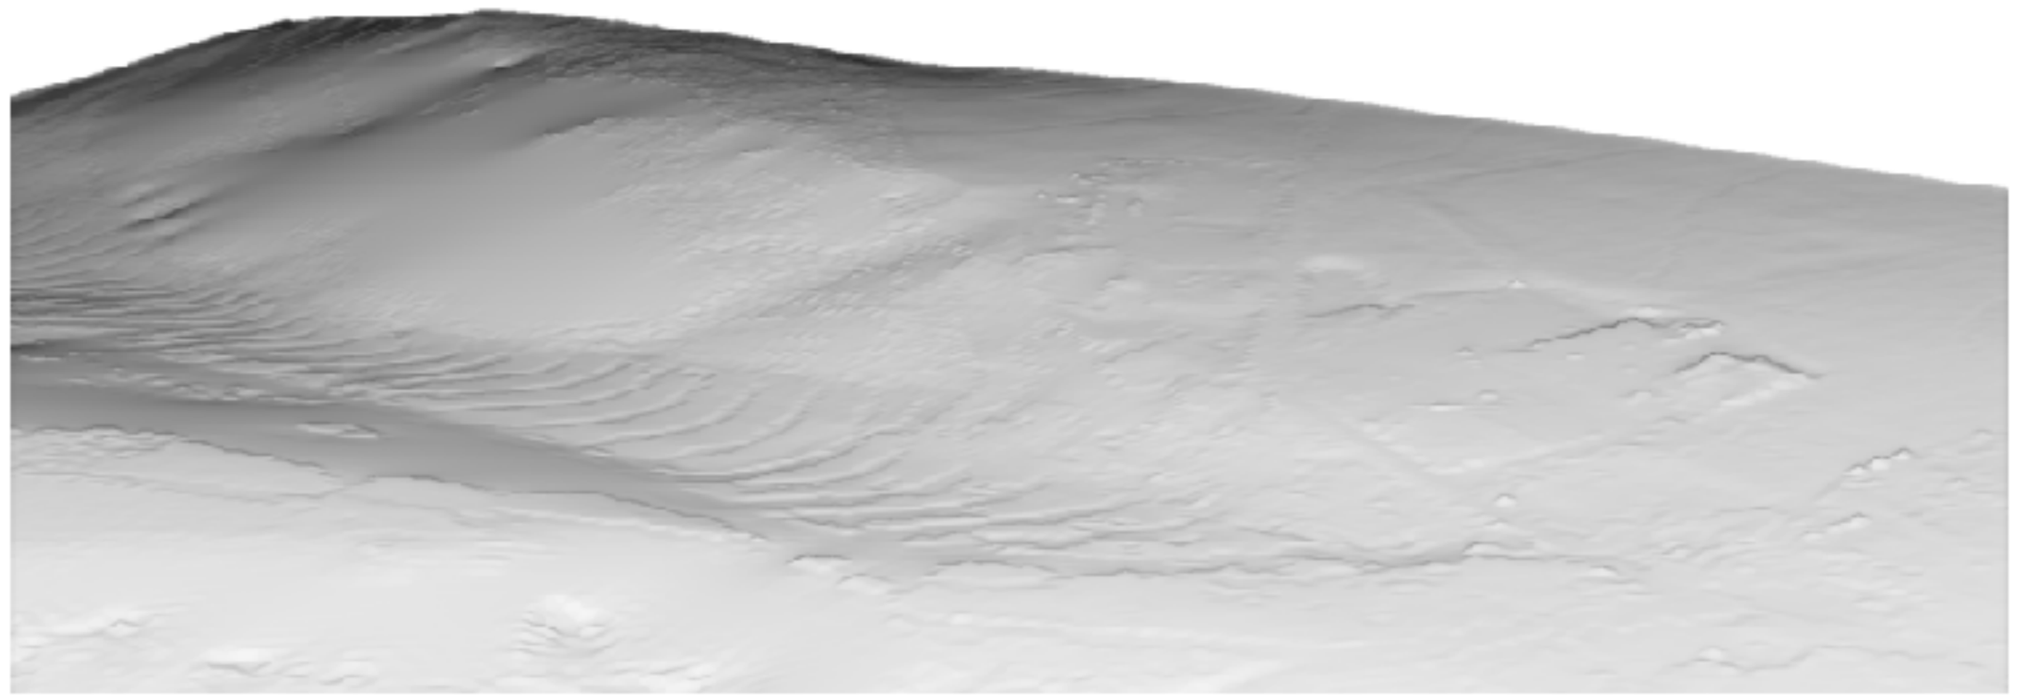
CSF: 2 outputs



(a) Original point cloud



(b) Output #1: the ground points (with the ground surface shown in grey)



(c) Output #2: the ground surface
